20. ABSTRACT (Continue on reverse side if necessary and identify by block number)

The New Naugatuck Reservoir Dam consists of an earth fill embankment with a concrete corewall, a spillway and spillway channel with an earthfill embankment dike. The dam is 790 ft. long including the spillway. Based upon the visual inspection at the site and past performance, the dam is judged to be in good condition. In accordance with the Corps of Engineers Guidelines for size (intermediate) and hazard (high) classification for the dam, the test flood is considered to be equivalent to the Probable Maximum Flood.

BRIEF ASSESSMENT

PHASE I INSPECTION REPORT

NATIONAL PROGRAM OF INSPECTION OF DAMS

Name of Dam:	NEW NAUGATUCK RESERVOIR DAM
	(LONG HILL RESERVOIR)
Inventory Number:	CT 00307
State Located:	CONNECTICUT
County Located:	NEW HAVEN
Town Located:	BETHANY
Stream:	BEACON HILL BROOK
Owner:	THE CONNECTICUT WATER COMPANY
Date of Inspection:	NOVEMBER 6, 1979
Inspection Team:	PETER M. HEYNEN, P.E.
•	MIRON PETROVSKY
	JAY A. COSTELLO
	HECTOR MORENO, P.E.

The New Naugatuck Reservoir Dam, built in 1914, consists of an earth fill embankment with a concrete corewall, a spillway and spillway channel with an earth fill embankment dike. The dam is 790 feet long including the spillway. The top of the dam (elevation 540.8) is 20 feet wide and is 80+ feet above the streambed of Beacon Hill Brook. The corewall has a top elevation of 537.8 or 3 feet below the top of the dam. The spillway, located at the left end of the dam, is 40.5 feet long at the crest and consists of a concrete ogee weir and a stone paved discharge channel. The dike is 310 feet long, 10 feet high and 10 feet wide at the top. The outlets are a 16 inch upper level outlet at the left side of the dam near the toe of the dike and a 12 inch low-level outlet at the downstream toe of the dam.

Based upon the visual inspection at the site and past performance, the dam is judged to be in good condition. No evidence of instability was observed in the dam or dike embankments. The condition of the spillway and outlet channels appear to be good. There are areas requiring attention and monitoring such as seepage along the downstream toe of the dam embankment.

In accordance with the Corps of Engineers Guidelines for size (Intermediate) and hazard (High) classification for the dam, the test flood is considered to be equivalent to the Probable Maximum Flood (PMF). Peak inflow to the reservoir is 5,400 cubic feet per second (cfs); peak outflow is 4,150 cfs with the dam overtopped 0.8 feet. The spillway capacity with the reservoir level to the top of the dam is 2,130 cfs, which is 51% of the routed test flood outflow.

It is recommended that the owner retain the services of a registered engineer to perform a more detailed inspection of the dam. Items of importance are; evaluation of the condition of the outlet pipes, origin and significance of seepage and wet areas at the toe of the dam and installation of piezometers to monitor the phreatic surface in the dam. Recommendations should be made by the engineer and implemented by the owner.

The above recommendations and further remedial measures which are discussed in Section 7, should be instituted within one (1) year of the owner's receipt of this report.

Peter M. Heynen, P.E.

1

Project Manager Geotechnical Cahn Engineers, Inc.

Edga B. Vinal, Jr., P.E. Senior Vice President Cahn Engineers, Inc.

This Phase I Inspection Report on New Naugatuck Reservoir Dam has been reviewed by the undersigned Review Board members. In our opinion, the reported findings, conclusions, and recommendations are consistent with the Recommended Guidelines for Safety Inspection of Dams, and with good engineering judgment and practice, and are hereby submitted for approval.

CHARLES G. TIERSCH, Chairman Chief, Foundation and Materials Branch Engineering Division

FRED J. RAVENS, Jr., Member Chief, Design Branch Engineering Division

SAUL C. COOPER, Member Chief, Water Control Branch Engineering Division

APPROVAL RECOMMENDED:

JOE B. FRYAR Chief, Engineering Division

PREFACE

This report is prepared under guidance contained in the Recommended Guidelines for Safety Inspection of Dams, for Phase I Investigations. Copies of these guidelines may be obtained from the Office of Chief of Engineers, Washington, D.C. 20314. The purpose of a Phase I Investigation is to identify expeditiously those dams which may pose hazards to human life or property. The assessment of the general condition of the dam is based upon available data and visual inspection. Detailed investigation, and analyses involving topographic mapping, subsurface investigations, testing, and detailed computational evaluations are beyond the scope of a Phase I Investigation; however, the investigation is intended to identify any need for such studies.

In reviewing this report, it should be realized that the reported condition of the dam is based on observations of field conditions at the time of inspection along with data available to the inspection team. In cases where the reservoir was lowered or drained prior to inspection, such action, while improving the stability and safety of the dam, removes the normal load on the structure and may obscure certain conditions which might otherwise be detectable if inspected under the normal operating environment of the structure.

It is important to note that the condition of a dam depends on numerous and constantly changing internal and external conditions, and is evolutionary in nature. It would be incorrect to assume that the present condition of the dam would necessarily represent the condition of the dam at some point in the future. Only through continued care and inspection can there be any chance that unsafe conditions will be detected.

Phase I inspections are not intended to provide detailed hydrologic and hydraulic analyses. In accordance with the established Guidelines, the Spillway Test Flood is based on the estimated "Probable Maximum Flood" for the region (greatest reasonably possible storm runoff), or fractions there of. Because of the magnitude and rarity of such a storm event, a finding that a spillway will not pass the test flood should not be interpreted as neccessarily posing a highly inadequate condition. The test flood provides a measure of relative spillway capacity and serves as an aid in determining the need for more detailed hydrologic and hydraulic studies, considering the size of the dam, its general condition and the downstream damage potential.

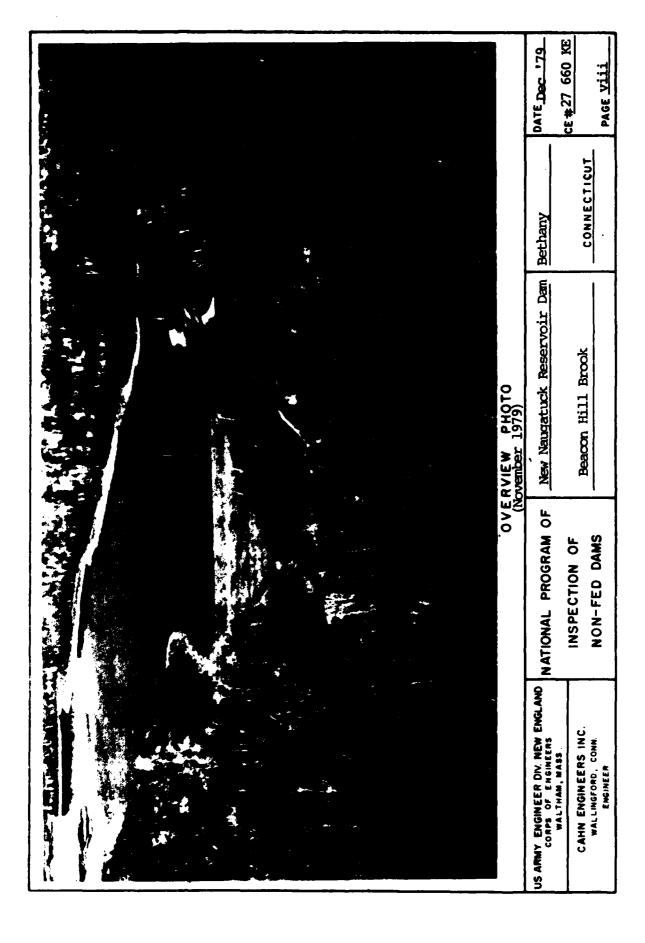

The Phase I Investigation does not include an assessment of the need for fences, gates, no-trespassing signs, repairs to existing fences and railings and other items which may be needed to minimize trespass and provide greater security for the facility and safety to the public. An evaluation of the project for compliance with OSHA rules and regulations is also excluded.

PHASE I INSPECTION REPORT

NEW NAUGATUCK RESERVOIR DAM

SECTION I - PROJECT INFORMATION

1.1 GENERAL

- a. Authority Public Law 92-367, August 8, 1972, authorized the Secretary of the Army, through the Corps of Engineers, to initiate a National Program of Dam Inspection throughout the United States. The New England Division of the Corps of Engineers has been assigned the responsibility of supervising the inspection of dams within the New England Region. Cahn Engineers, Inc. has been retained by the New England Division to inspect and report on selected dams in the State of Connecticut. Authorization and notice to proceed were issued to Cahn Engineers, Inc. under a letter of October 15, 1979 from William E. Hodgson, Jr. Colonel, Corps of Engineers. Contract No. DACW 33-79-C-0059 has been assigned by the Corps of Engineers for this work.
- b. Purpose of Inspection Program The purposes of the program are to:
 - 1. Perform technical inspection and evaluation of non-federal dams to identify conditions requiring correction in a timely manner by non-federal interests.
 - 2. Encourage and prepare the States to quickly initiate effective dam inspection programs for non-federal dam.
 - 3. To update, verify and complete the National Inventory of Dams.
- c. Scope of Inspection Program The scope of this Phase I inspection report includes:
 - 1. Gathering, reviewing and presenting all available data as can be obtained from the owners, previous owners, the state and other associated parties.
 - 2. A field inspection of the facility detailing the visual condition of the dam, embankments and appurtenant structures.
 - 3. Computations concerning the hydraulics and hydrology of the facility and its relationship to the calculated flood through the existing spillway.
 - 4. An assessment of the condition of the facility and corrective measures required.

It should be noted that this report does not pass judgement on the safety or stability of the dam other than on a visual basis. The inspection is to identify those features of the dam which need corrective action and/or further study.

1.2 DESCRIPTION OF PROJECT

- a. Location The dam is located on Beacon Hill Brook in a rural area of the town of Bethany, County of New Haven, State of Connecticut. The dam is shown on the Mount Carmel USGS Quadrangle Map having coordinates latitude N 41 27.9 and longitude W 72 58.1.
- b. Description of Dam and Appurtenances The project consists of a 790+ foot long earth fill embankment dam, a 40.5 foot long spillway at the left end of the dam and a spillway channel with a 310 foot long earth fill embankment dike.

The dam has a top elevation of 540.8, which is 80+ feet above the streambed of Beacon Hill Brook and 6 feet above the spill-way crest. The top of the dam is 20 feet wide and has a grass cover. The upstream slope is riprapped to within 2+ feet of the crest and has an inclination of 2 horizontal to 1 vertical. The downstream slope has a grass cover, is inclined at 2 horizontal to 1 vertical and has a 5 foot wide berm at elevation 502+. A concrete corewall extends along the axis of the dam for the entire length of the embankment and has a top elevation of 537.8.

The dike is located at the left end of the dam and forms the spillway channel (See Sheet B-1). The dike is 310 feet long, 10 feet high and 10 feet wide at the top. The slope on the channel side is inclined at 1.5 horizontal to 1 vertical and has riprap placed to within 2 feet of the top of the dike. The back slope is grass covered and is also inclined at 1.5 horizontal to 1 vertical. The top of the dike is grass covered and ranges in elevation from 540+ at the upstream end to 538+ at the downstream end.

The spillway consists of a concrete ogee shaped weir and a spillway channel. The weir is 40.5 feet long, has a crest elevation of 534.8 and concrete training walls with a top elevation of 540.8. The spillway channel is 40+ feet wide, 310 feet long and has stone paving along the channel $f\overline{l}$ oor.

The low-level outlet consists of 20 inch and 16 inch inlet valves, a 20 inch cast iron pipe which extends to a gate house at the downstream toe of the dam, and a series of outlet valves. The 20 inch inlet valve is at elevation 485.5 and the 16 inch inlet valve is at 504.8. These valves are controlled with operating handles from a chamber located at the central part of the top of the dam. At the downstream gate house there are four gate valves; a 20 inch valve, a 12 inch valve and reducer, a 12 inch automatically controlled valve, and a 12 inch manual valve at invert elevation 464+ (See page B-12). The original 20 inch outlet pipe has been plugged and a new 12 inch pipe has been installed with the outlet to the left side of the gate house.

L

The upper level outlet consists of a 16 inch inlet valve at elevation 524.0 and a 16 inch automatically controlled outlet valve at invert elevation 520.3, which is housed in a concrete chamber at the toe of the dike about 100 feet from the spillway. The upper level inlet valve is controlled from a chamber located at the top left end of the dam. There is also an 8 inch outlet pipe (upstream invert elevation 530.8) located to the left of the right spillway training wall. The pipe is controlled with a hand operated valve stem located in the spillway approach channel 3 feet upstream from the spillway weir and 1 foot from the right training wall. The purpose of this pipe is unknown and it is presently not in use. There is also a mudgate which is located just below the 20 inch inlet valve.

There are two masonry channels; one from the upper level outlet and a second from the spillway channel (See Sheet B-1). These two channels meet approximately 200 feet downstream from the upper level outlet valve chamber to form the lower spillway channel which extends another 400+ feet downstream to a small concrete dam and compensating pond. The channel from the upper level outlet is about two feet wide and the lower spillway channel is approximately 4 feet wide. Both channels have stone masonry sidewalls and a mortar lined floor.

- c. <u>Size Classification</u> (INTERMEDIATE) The dam impounds 2,140 acre-feet of water with the reservoir level at the top of the dam, which at elevation 540.8, is 80+ feet above the streambed. According to the Recommended Guidelines, a dam with this height and storage capacity is classified as intermediate in size.
- d. <u>Hazard Classification</u> HIGH If the dam were breached, there is potential for loss of life and extensive property damage to at least 4 houses which are situated 6 to 13 feet above the streambed and located along Beacon Hill Brook and Route 63 between 3000 and 7000 feet downstream.
 - e. Ownership Connecticut Water Company
 93 West Main Street
 Clinton, Connecticut
 Mr. Kenneth Kells (203) 669-8636
 - f. Operator Mr. William T. Dunn
 250 Meadow Street
 Naugatuck, Connecticut (203) 729-8241
 - g. Purpose of Dam Water Supply
- h. <u>Design and Construction History</u> The following information is believed to be accurate based on the plans and correspondence available. The dam was designed by George C. Ham and constructed by the Connecticut Water Company in 1914. The flashboards at the spillway weir were permanently removed in October 1969. The lower spillway channel, which was damaged by high water, ice and freezing in January, 1979, was reconstructed in the spring of the same year.

i. Normal Operational Procedures - When the level of Twitchell Reservoir (downstream) drops below acceptable levels, the water level is re-established by flows from the outlets at New Naugatuck Reservoir. The upper level outlet is opened first and when the head in New Naugatuck Reservoir drops 4+ feet, the low-level outlet is used. (For more details see Section 4.1). The 16 inch inlet valve for the low-level outlet is normally open and the 20 inch valve is kept closed. The 16 inch inlet valve for the upper level outlet is also kept open and flow through this outlet is controlled from the concrete chamber at the downstream toe of the dike.

1.3 PERTINENT DATA

- a. <u>Drainage Area</u> 2.6 square miles of relatively undeveloped rolling wooded terrain.
- b. Discharge at Damsite Discharge is over the spillway, through the 8 inch pipe at the spillway and through the upper level or low-level outlets.
 - 1. Outlet Works (conduits):

8 inch outlet @ spillway weir: [Inknown
	66 cfs @ 77 feet of head
	25 cfs 0 21 feet of head

SECTION 2: ENGINEERING DATA

2.1 DESIGN

- a. Available Data The available data consists of plans, operations and maintenance manual and correspondence. The plans are design drawings from 1913 and as-built drawings dated 1914, both by George C. Ham, C.E. The correspondence consists of storage computations and lake level readings from the Connecticut Water Company, general specifications by George C. Ham and obtained from the Connecticut State Library, and inventory sheets from the Connecticut Department of Environmental Protection.
- b. Design Features The drawings and correspondence indicate the design features stated previously in this report.
- c. <u>Design Data</u> There were no engineering values, assumptions, tests results or calculations available for the original construction of the dam.

2.2 CONSTRUCTION

- a. Available Data The available construction data consists of the as-built drawings and general specifications as listed in 2.1.a.
- b. Construction Considerations No information was available for any problems or changes made during construction of the dam.

2.3 OPERATIONS

Reservoir level readings are taken once a week. According to the owner, the dam spillway capacity has never been exceeded or the dam overtopped. A short operations manual and water level readings prepared by the Connecticut Water Company are presented in Appendix B.

2.4 EVALUATION

- a. Availability Existing data was provided by the Connecticut Department of Environmental Protection, Connecticut State Library and The Connecticut Water Company. The owner made the project available for visual inspection.
- b. Adequacy The limited amount of detailed engineering data available was generally inadequate to perform an in-depth assessment of the dam, therefore the final assessment of this dam must be based primarily on visual inspection, performance history, hydraulic computations of spillway capacity and approximate hydrologic judgements.
- c. <u>Validity</u> A comparison of record data and visual observations reveals no observable significant discrepancies in the record data.

SECTION 3: VISUAL INSPECTION

3.1 FINDINGS

a. General - The general condition of the project is good. The inspection did reveal some areas requiring maintenance and monitoring. The reservoir level was 528.0+ at the time of our inspection, i.e. 12+ feet below the top of the dam.

b. Dam

<u>Crest</u> - The top of the dam shows no signs of misalignment, visible cracks or erosion (Photos 1 and 2).

Downstream Slope - There was no misalignment or sloughing noted on this slope (Photo 1). An extensive wet area was observed at the left end of the toe of the dam, just above the berm (Photos 12, 13, 14). Seepage from this area is flowing along the toe and down toward the gate house and low-level discharge channel. The stream flowing out from this area had a measured discharge approximately 30 gallons per minute (Photo 11).

Erosion was observed on the downstream slope and toe of the dam about 15 feet from the left side of the gate house. The ground in this area was wet and soggy.

Spillway - The concrete at the spillway weir and training walls is in good condition. No cracks or efflorescence was observed (Photos 3 through 5). The expansion joints of the training walls appear to be watertight.

The stone paved floor of the spillway channel is in good condition. Tall weeds growing on the channel floor were observed (Photos 4 and 5).

The left slope of the spillway channel is natural ground. There is riprap and a short dry-laid stone wall at the toe of this slope adjacent to the left spillway training wall. There is deterioration of this masonry wall, with some of the stones loose and falling into the spillway channel. The right slope of the spillway channel is the riprapped and grassed slope of the dike. This slope was in good condition (Photo 5). No erosion on the top or downstream slope of this dike was noted (Photo 6).

The lower spillway channel and the channel from the upper level outlet appear to be newly constructd with no cracks or deterioration observed in the channels.

c. Appurtenant Structures - The chambers (on the top of the dam) for operating the upper level and low-level inlet valves, the upper level outlet valve chamber and the low-level gate house are all in good condition (Photos 1, 2 and 10). No cracks or spalling of the concrete was observed. A 2 inch deep layer of water, probably from recent rainfall was noted on the floor of the operating chamber for the low-level intake valve. Water, caused by leaking valves, was also noted at the bottom of the concrete chamber at the low-level gatehouse.

The masonry walls and stone paved portion of the outlet channel at the low-level gatehouse are in good condition.

- d. Reservoir Area The area surrounding the reservoir is generally wooded and undeveloped.
- e. <u>Downstream Channel</u> The downstream channel runs in the natural streambed of the old Beacon Hill Brook. It is mostly undeveloped, steep-sided and wooded to the initial impact area.

3.2 EVALUATION

Based upon the visual inspection, the project is assessed as being generally in good condition. The following features which could influence the future condition and/or stability of the project were identifed.

- Seepage through the left portion of the dam can potentially increase in flow, leading to erosion and sloughing of the downstream slope and instability of the dam.
- Erosion on the downstream slope and toe to the left of the gate house could lead to structural problems in this area.
- 3. Pressure in the upper and lower outlet pipes, caused by leaving the upstream valves open and controlling the flow through these pipes with the downstream valves, could cause seepage into and through the embankment.
- 4. The damaged riprap and retaining wall at the left side of the spillway channel could result in erosion of this slope and the spillway training wall during high flows through the spillway channel.
- 5. Water on the floor of the low-level intake valve chamber could increase the deterioration process of the concrete in the chamber due to freeze-thaw cycles.

SECTION 4: OPERATIONAL PROCEDURES

4.1 REGULATING PROCEDURES

By operating a three-way switch in the lower gate house, control of the valves at the dam can be set for automatic upper level outlet, automatic low-level outlet or manual control at each The switch is usually set for automatic control at the outlet. upper outlet. When the water level in Twitchell Reservoir (1000 feet downstream) drops 14 inches, the upper level automatically controlled 16 inch outlet valve at the dam opens to refill Twitchell. When the water level at New Naugatuck Reservoir drops 4+ feet, there is no longer enough head to operate this valve and it must be opened manually and flow controlled at the inlet valve. Automatic control is now switched to the lower outlet valve, which also augments Twitchell Reservoir. When Twitchell Reservoir reaches a sufficient level, the lower valve shuts down and the upper level valve is returned to automatic control, using the switch in the gate house. Of the two inlets for the low-level outlet, only the 20 inch (el. 504.8) valve is open.

4.2 MAINTENANCE OF DAM

The dam is patrolled daily and checked for debris and obstacles in the spillway and the stream leading to Twitchell Reservoir. Also, a check is made for unusual trespassing, floating debris and animal burrows. The grass is cut every month (weather permitting) and brush removed. Trees are not allowed to infringe upon the slopes of the embankments.

4.3 MAINTENANCE OF OPERATING FACILITIES

Valves and gates are flushed and cleaned once a year and all outlets checked.

4.4 DESCRIPTION OF ANY FORMAL WARNING SYSTEM IN EFFECT

Any problem situations arising at the dam are reported to the Connecticut Water Company Division Manager. Other than this, no formal warning system is in effect.

4.5 EVALUATION

The operation and maintenance procedures are generally good, however there are some items requiring improvement. A formal warning system should be developed and implemented within the time frame indicated in Section 7.1c. Recommended operation and maintenance improvements are presented in Section 7.

SECTION 5: HYDRAULIC/HYDROLOGIC

5.1 EVALUATION OF FEATURES

- a. General The watershed is 2.6 square miles of relatively undeveloped rolling wooded terrain. The dam is an earth embankment which is a high surcharge storage low spillage project. The dam develops sufficient storage to reduce the Probable Maximum Flood (PMF) from about 5,400 cfs to 4,150 cfs (about a 23% reduction) and the 1/2 PMF from about 2,700 cfs to 1,680 cfs (about a 38% reduction).
- b. <u>Design Data</u> No computations could be found for the original dam construction.
- c. Experience Data No information was found to indicate that there have been any serious problems with the dam, and it was reported that the dam has not been overtopped. The maximum height of water over the spillway since removal of the flashboards in October 1969 was reported as 20 inches on January 25, 1979. The maximum reservoir level before removal of the flashboards was recorded as 32.5 inches over the spillway crest in February 1964.
- d. <u>Visual Observations</u> The dam embankment is well maintained. A new masonry discharge channel has been recently constructed between the spillway channel and the compensating pond, 600 feet downstream.
- e. Test Flood Analysis Based upon the Army Corps of Engineers' "Preliminary Guidance for Estimating Maximum Probable Discharge", dated March 1978, the watershed area (2.6 square miles) and classification (rolling), a Probable Maximum Flood (PMF) of 5400 cfs, or 2100 cfs per square mile, is expected at the dam site. In accordance with the size (intermediate) and hazard (high) classification, the test flood is considered to be equivalent to the PMF.

Peak inflow to the reservoir at the PMF is 5,400 cfs and peak outflow is 4,150 cfs with the dam overtopped 0.8 feet (Appendix D-13). Based upon our hydraulic computations, the spillway capacity to top of dam is 2130 cfs which is approximately 51% of the routed test flood outflow. Peak inflow at the ½ PMF 2,700 cfs, peak outflow will be 1680 cfs with the water level in the reservoir to elevation 539.8.

f. Dam Failure Analysis - Utilizing the April, 1978, "Rule of Thumb Guidance for Estimating Downstream Dam Failure Hydrographs", the peak failure outflow from the dam breaching would be 103,000 cfs. A breach of the dam would result in a rise of about 20 feet in the water level of the stream at the initial impact area, which corresponds to an increase in the water level from a depth of 6.5 feet just before the breach, to a depth of 26.2 feet just after the breach. The rapid 20+ foot increase in the water level at the initial impact area would inundate at least four houses along Beacon Hill Brook to a depth of 13 to 20 feet. These houses are located 6 to 13 feet above the streambed between 3000 and 7000 feet downstream from the dam (See Sheet D-1). There are other structures further downstream which might be subject to flooding as the stream passes through a heavily populated area in the suburbs of Waterbury.

SECTION 6: STRUCTURAL STABILITY

6.1 EVALUATION OF STRUCTURAL STABILITY

- a. <u>Visual Observations</u> The visual inspection did not reveal any indications of immediate stability problems. There are areas of seepage, masonry deterioration and erosion as described in Section 3, however they are not considered stability concerns at the present time.
- b. <u>Design and Construction Data</u> There is not adequate design and construction data available to permit an in-depth assessment of the structural stability of the project or the appurtenant structures.
- c. Operating Records The available operating records do not reveal any indications of instability in the dam since its construction in 1914.
- d. <u>Post Construction Changes</u> The only indication of post-construction changes of the project is reconstruction of the lower spillway channel in 1979 and the installation of the 12 inch outlet at the low-level gatehouse.
- e. <u>Seismic Stability</u> The project is in Seismic Zone l and according to the Recommended Guidelines, need not be evaluated for seismic stability.

L

SECTION 7: ASSESSMENT, RECOMMENDATIONS AND REMEDIAL MEASURES

7.1 PROJECT ASSESSMENT

a. Condition - Based upon the visual inspection and past performance, the project appears to be in good condition. No evidence of structural instability was observed. The dam embankment is in good condition, although there are areas which require maintenance and monitoring, such as seepage along the downstream toe of the dam and erosion to the left of the low-level gatehouse.

Based upon the Army Corps of Engineers' "Preliminary Guidance for Estimating Maximum Probable Discharge" dated March, 1978 and hydraulic/hydrologic computations, the peak inflow to the reservoir is 5,400 cfs and the peak outflow is 4,150 cfs with the dam overtopped 0.8 feet. Based upon our hydraulic computations, the spillway capacity is 2,130 cfs, which is equivalent to approximately 51% of the routed test flood outflow.

- b. Adequacy of Information The information available is such that an assessment of the condition and stability of the project must be based solely on visual inspection, past performance of the project, and sound engineering judgement.
- c. Urgency It is recommended that the measures presented in Section 7.2 and 7.3 be implemented within one year of the owner's receipt of this report.

7.2 RECOMMENDATIONS

It is recommended that further studies be made by a registered professional engineer qualified in dam design and inspection pertaining to the following:

 Flow through the 16 inch upper level and 20 inch low-level outlets should be regulated with the upstream valves. This will eliminate pressures in these pipes within the embankment and therefore, reduce the possibility of seepage into the embankment from these pipes.

Ł

- Inspection of the project during a period of high head and make any necessary recommendations. Items of particular importance are as follows:
 - (a) The origin and significance of the wet area and seepage at the toe of the dam. This should include installation of weirs and rain gauges, and monitoring of seepage flows at various reservoir elevations.
 - (b) Installation of piezometers for determination and monitoring of the phreatic surface in the dam, and for evaluation of the permeability of the concrete corewall.

3. Evaluation of the condition of the 16 inch and 20 inch outlet pipes. This may be done by closing the upstream valve, opening the downstream valve and checking for seepage flow into the pipe from the embankment.

7.3 REMEDIAL MEASURES

- a. Operation and Maintenance Procedures The following measures should be undertaken within the time period indicated in Section 7.1.c, and continued on a regular basis.
 - 1. Round-the-clock surveilance should be provided by the owner during periods of unusually heavy precipitation and high project discharge. The owner should develop and implement a downstream warning system to be used in case of emergencies at the dam.
 - 2. The present program of inspection should be continued and should include an annual inspection by a registered professional engineer qualified in dam inspection.
 - Seepage and wet areas at the left side of the toe of the dam should be monitored periodically (as recommended by the engineer) to measure any changes in the seepage flow.
 - 4. Erosion on the downstream slope of the dam near the gate house should be filled with suitable material, compacted and slope protection placed.
 - 5. The damaged stone wall of the spillway channel, adjacent to the left spillway training wall, should be repaired to prevent erosion in the future.
 - 6. Drain pipes should be installed in the floor of the concrete valve chambers and the gate house to eliminate deterioration of the concrete from accumulated water.
 - 7. The cutting of grass and brush on the crest and slopes of the dam, the spillway dike and the floor of the spillway channel should be continued as part of the routine maintenance procedure.

7.4 ALTERNATIVES

This study has identified no practical alternatives to the above recommendations.

D UPLICATIONS. GENERAL SPECIFICATIONS.

GENERAL SPECIFICATIONS.

Dam to be located about 200 feet below the function of Long inflownof Arthory

Will and Lacy brooks. Spilly elevation 384 city datum.

Top of dam 6 feet above water. Vaximum depth of water 50 feet. Top length of dam to spilly 720 feet. Width of spilly 40 feet.

EXCAVATION.

All stumps, roots, soil or perishable material to be removed from site. Center trench to be dug to rock or inte hard pan to a depth equal to 2/2 the depth of water ever the surface.

Additional public trench near inner too as shown.

Rock exposed in center trench to be cleaned and all seams grouted. Rock under core wall to be channeled from 1/2 to 2 feet or to a sound surface.

FILL.

Only sound materials to be used in the fill. Hard

pan er sand, gravel and clay properly mixed shall be spread

in 6 inch courses, sprinkled and rolled with a ten ten grooved

reller. Selected material to be used on the up stream side

of the core wall.

Sections which cannot be rolled will be puddled by sprinkling the earth into one foot of standing water.

No stones larger than 4 inches diameter to be used except near the toe.

CORE WALL & SPITLWAY.

with a 1/2 inch per foot batter on each site. A 6 inch by
12 inch tengue to rise to 3 feet above the water line.

Concrete to be mixed 1 part sement (Pertland), 2 1/8 te $_{\mathrm{B}\rightarrow4}$

to 3 parts sand and 5 to 6 parts broken stone or gravel or as the sand and gravel or stone voids require.

In the wider parts of the wall and in the spillway

250 of clean plum stones up to 1 cubic foot may be used.

Stones to be wet and placed at least 6 inches apart.

All joints vertical and horizontal shall be keyed and honded with steel rods.

WASTF PIPTS %c.

One line of 20 inch cast iron pipe with a 18 inch branch will be laid in a trench union the dam, also one line of 13 inch for a service pipe about 12 feet below the water level.

All pipe lines to be bedded and encased with at least dinches of concrete with cut off walls at joints as shown on plans.

Valves to be operated by rods laid in pipes up the slopes, or on brackets.

Inner slope to be paved, outer slope soiled or sadded as shown on plan.

The dam will be built in conformity with these specifications and the accompanying plans and in detail as directed by the environe, George C. Ham, under whose supervision and to whose approval all the work shall be done.

OPERATIONS & MAINTENANCE MANUAL LONG HILL RESERVOIR

Long Hill Reservoir is a public water distribution reservoir for the Naugatuck Division of The Connecticut Water Company. The dam is located at the south end of the reservoir in the town of Bethany and its access is from Route 63. The reservoir impounds water in the town of Bethany and Prospect. See attached map. Long Hill Reservoir has a surface area of 82.5 acres and a watershed of approximately 2.47 square miles. At the spillway crest (535 feet U.S.G.S.) the storage capacity of the reservoir is 506 million gallons. The estimated safe yield of Long Hill is 1.88 MGD. This distribution reservoir supplies water to Twitchell Reservoir, a small compensating reservoir, which operates on the system gradient.

The dam at Long Hill Reservoir is a straight earth embankment with a concrete core wall. The dam is approximately 793 feet long with a maximum height of 71 feet. The grassed crest averages 20.0 feet in width. The upstream face is gradually sloping with rip rap protection from the base to the crest. The spillway is a 40'-10½" long broadcrested overflow weir situated at the extreme east end of the dam. The spillway has a freeboard of 72". Two pressure equalizers are bolted to either end of the spillway. These pipes protect the toe of the slope by preventing a vacuum from forming when water is spilling.

Besides the spillway, the water flow is controlled by two electrically operated Ross valves, model 50 FWR. A 16" Ross valve, the upper automatic, is housed approximately 100 feet from the spillway in a concrete vault. The lower automatic is a 12" Ross valve located at the toe of the dam approximately 525 feet from the spillway. When the level of Twitchell drops approximately 14 inches, this level can be adjusted as required, the upper automatic opens to refill Twitchell. It usually takes about 10 minutes for this flow of water to have an effect on Twitchell. When the water level drops about four feet in Long Hill, there no longer is enough head to operate the upper automatic. Operations call for the 16" Ross valve to be manually opened and the flow to Twitchell to be adjusted using the 16" Ludlow gate valve in the reservoir. With the upper automatic in the manual position, power is switched over to the lower automatic, and that too augments Twitchell. The purpose of both feeding Twitchell at the same time is to improve quality. When the water level drops below the invert

of the upper automatic (524 feet), Twitchell is then fed by the lower automatic. The lower automatic has two inverts, a 16" Ludlow gate valve at elevation 504.75 which is opened, and a 20" Ludlow gate valve at elevation 485.43 which is closed. See plan #1. Besides these invert gate valves, two others exist. An 8" gate exists at the northwest corner of the spillway at elevation 531. See plan #2. Also a mud gate, size and invert unknown, exists below the 20" Ludlow gate valve. Very little is presently known about the operation capability of either of these valves. The one near the spillway is visible when the reservoir is not spilling.

Present operations at the dam require whichever altitude valve is in service to open in case of power failure. When Twitchell is being filled by the upper automatic the lower automatic is opened and a 12" tapping valve in the wooden shed is cracked open to allow for some flushing of the line. The average summer drawdown is about five feet. During the drought of the mid 60° s, the level of the reservoir was down $23\frac{1}{2}$ feet. Flood flows have been read as high as 536.83 feet (20°) over the spillway. This occurred on January 25, 1979.

The entrance to Long Hill Reservoir is fenced and the access gate is locked at all times. The reservoir is patrolled daily at various hours. The patrol of the area includes:

- a.) A check of the spillway for debris and obstacles
- b.) A check of the stream feeding Twitchell
- c.) Any unusual activities, e.g. motorcycles, horseback riders, dead animals, animal burrows, etc.

Trespassing is not allowed on Water Company lands. All problems and violations are reported to the Division Manager as soon as possible. In addition to the patrolman, the pump station attendant inspects and maintains the aeration equipment at the reservoir.

Inspections of the embankments and foundations are at regular intervals using form CWC E-19. A copy of a typical inspection report is attached. Tree growth along the artificial fill area is closely monitored and is not allowed to encroach upon the fill area. Seasonal maintenance is done as required. Because chemical spills along Route 69 can be a problem, contingency plans have been drawn up in cooperation with local fire and police departments. Water Company lands near the reservoir are managed by Connwood of Rockfall, CT.

Copies of this manual are distributed to the Division Manager and Engineering Department.

LONG HILL RESERVOIR Contingency Plan for Chemical Spills

Oil or chemical spills on Route 69 affecting the reservoirs on the Marks Brook watershed would require immediate action. The reservoirs that would be affected are Long Hill Reservoir and Twitchell.

The number one priority of a chemical spill in this area is to keep the contamination out of Twitchell Reservoir. This priority is accomplished by closing the gate valves to contain the spill to a minimum number of reservoirs. See sketch. Generally, this procedure would be the responsibility of the Reservoir Inspector. He must react as quickly as possible to keep time to a minimum in isolating the source of contamination from the water supply. After containing the pollution, he shall notify his supervisor and begin cleanup operations immediately.

Re: New Naugatuck Reservoir Dam

The following are excerpts pertaining to the New Naugatuck Reservoir Dam taken from correspondence obtained from the files of the Connecticut Water Company.

1. To: Files

From: K.W. Kells Date: Oct. 21, 1976

"Below are notes from my inspections of our dams with John Roberts of the Hartford Insurance Group."

- I. Long Hill with W. Dunn and W. Hill Oct. 14, 1976
 - a). Seep exists on east side of dam in area where east inlet pipe is located. Had existed for some time.
 - existed for some time.
 b). Next clearing of trees along the spillway outlet canal should include one more row of trees and one tree at south end west side of canal. Failure of canal wall during high runoff could cause erosion on downstream slope of dam.
- To: William F. Guillaume, Connecticut Water Company From: John A. Roberts, Hartford Insurance Company Date: February 13, 1978

Dear Mr. Guillaume:

This letter will confirm Ken Kells and my visits to the dams during the month of January, 1978, and to thank Ken for his time and the courtesies extended to me.

During these visits, we were accompanied by the Connecticut Water employees who have been selected and will be conducting the monthly inspections (other than the semi-annual months in which Ken conducts the inspections).

Cahn Engineers Inc.

In regards to those other Connecticut Water employees, I would like to mention at this time that I felt Ken provided sufficient guidance and training in what we were trying to accomplish during the inspections, use of the checklist that he developed, explanation of the terms on the checklist, and in general, how to carry out the visual inspections.

You more than likely already have the results of this survey from Ken and more than likely his report is more in depth and contains items that this letter does not, but I hope that there are no flagrant disagreements in our observations. This was the first time that we conducted the survey during the winter and it did allow us to make some observations without plant growth, but in other cases, we were not able to observe some areas that we wanted, due to snow and/or ice cover;

LONG HILL RESERVOIR

Seep in the toe of the slope on the east side could not be observed due to snow covering.

Ken felt that additional trees should be removed and directed Mr. Hill and Mr. Rahn to cut them this spring.

CAHN ENGINEERS, INC.

Day A. Costello Project Engineer

8.	Blackstone River.	43,000	416	200
9.	Quinebaug River	55,000	331	330

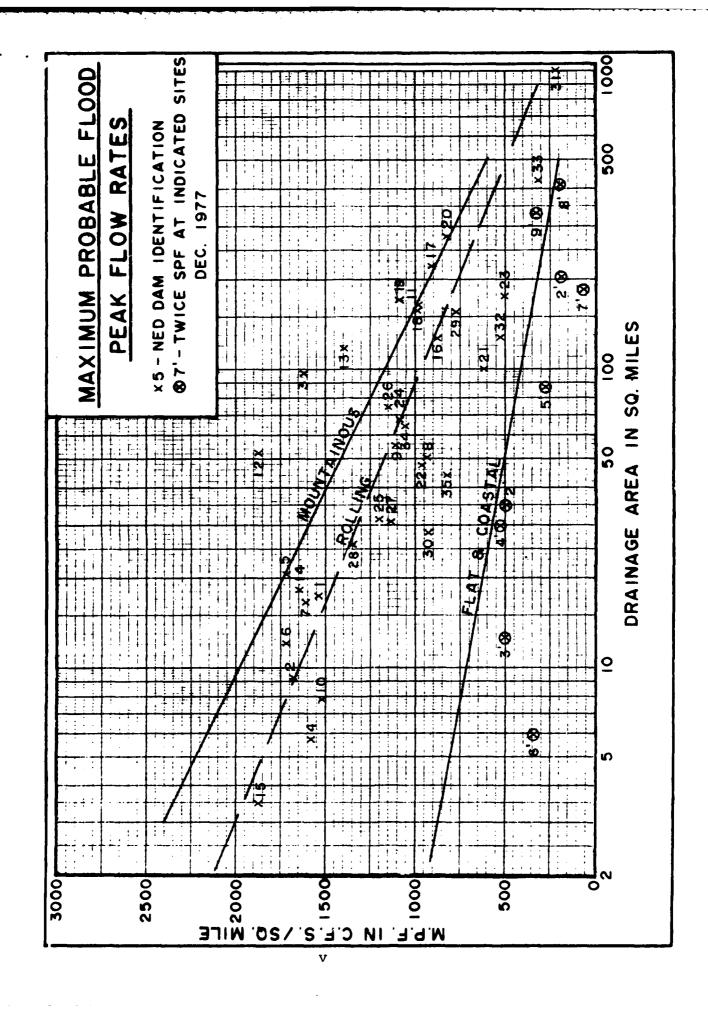

ON MAXIMUM PROBABLE DISCHARGES

- STEP 1: Determine Peak Inflow (Qp1) from Guide Curves.
- STEP 2: a. Determine Surcharge Height To Pass ''Qp1''.
 - b. Determine Volume of Surcharge (STOR1) In Inches of Runoff.
 - c. Maximum Probable Flood Runoff In New England equals Approx. 19", Therefore:

$$Qp2 = Qp1 \times (1 - \frac{STOR1}{19})$$

- STEP 3: a. Determine Surcharge Height and "STOR2" To Pass "Qp2"
 - b. Average "STOR1" and "STOR2" and Determine Average Surcharge and Resulting Peak Outflow "Qp3".

SURCHARGE STORAGE ROUTING SUPPLEMENT

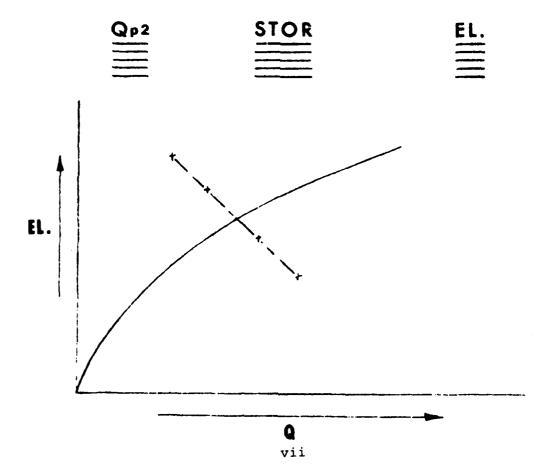

- STEP 3: a. Determine Surcharge Height and "STOR2" To Pass "Qp2"
 - b. Avg "STOR1" and "STOR2" and Compute "Qp3".
 - c. If Surcharge Height for Qp3 and "STORAVG" agree O.K. If Not:
- STEP 4: a. Determine Surcharge Height and "STOR3" To Pass "Qp3"
 - b. Avg. "Old STORAVG" and "STOR₃" and Compute "Qp4"
 - c. Surcharge Height for Qp4 and "New STOR Avg" should Agree closely

SURCHARGE STORAGE ROUTING ALTERNATE

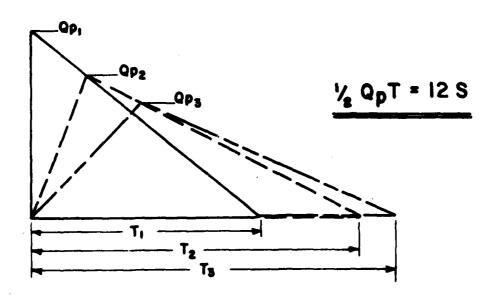

$$Q_{p2} = Q_{p1} \times \left(1 - \frac{STOR}{19}\right)$$

$$Q_{p2} = Q_{p1} - Q_{p1} \left(\frac{STOR}{19}\right)$$

FOR KNOWN Qp1 AND 19" R.O.

"RULE OF THUMB" GUIDANCE FOR ESTIMATING DOWNSTREAM DAM FAILURE HYDROGRAPHS

STEP 1: DETERMINE OR ESTIMATE RESERVOIR STORAGE (S) IN AC-FT AT TIME OF FAILURE.

STEP 2: DETERMINE PEAK FAILURE OUTFLOW (Qp1).

W_b= BREACH WIDTH - SUGGEST VALUE NOT GREATER THAN 40% OF DAM LENGTH ACROSS RIVER AT MID HEIGHT.

Yo = TOTAL HEIGHT FROM RIVER BED TO POOL LEVEL AT FAILURE.

STEP 3: USING USGS TOPO OR OTHER DATA, DEVELOP REPRESENTATIVE STAGE-DISCHARGE RATING FOR SELECTED DOWNSTREAM RIVER REACH.

STEP 4: ESTIMATE REACH OUTFLOW (Q_{p2}) USING FOLLOWING ITERATION.

- A. APPLY Q_{p1} TO STAGE RATING, DETERMINE STAGE AND ACCOPMANYING VOLUME (V_1) IN REACH IN AC-FT. (NOTE: IF V_1 EXCEEDS 1/2 OF S, SELECT SHORTER REACH.)
- B. DETERMINE TRIAL Qp2.

$$Qp_2(TR|AL) = Qp_1(1-\frac{V}{5})$$

- C. COMPUTE V2 USING QD2 (TRIAL).
- D. AVERAGE V₁ AND V₂ AND COMPUTE Q_{p2}.

 $Qp_2 = Qp_1 \left(1 - \frac{V_{max}}{8}\right)$

STEP 5: FOR SUCCEEDING REACHES REPEAT STEPS 3 AND 4.

APRIL 1978
